

Fixture Delta Delta architectural overview

This PDF fixture exercises the Tika PDF path for RAG-01.

It is deterministic synthetic engineering content and is safe to commit.

Overview

The Delta platform is a distributed request router with pluggable transports, configurable retry policies, and first-class observability. It targets latency-sensitive service meshes and polyglot microservice estates where per-request tenancy must be strongly enforced.

Core Components

The control plane publishes routing intent to every data plane node. Data plane nodes are stateless and can be rolled without draining. Observability hooks emit structured traces and metrics by default.

Deployment

Delta is packaged as a container image with a sidecar companion. The sidecar handles credential rotation and health signals. A single Helm chart provides production and staging profiles.

Security

Mutual TLS is the default transport, with rotating certificates issued from an internal certificate authority. Audit logs are emitted to a durable pipeline separate from application telemetry.
